BASELINE. Implant-supported prosthetic restorations to be done in a condition of lack of occlusal space due to the passive eruption of the opponents.

Two screw-retained temporary crowns were created. A silicone layer was used to mimic the gingiva.
A slight tissue ischemia was induced by the insertion of temporary crowns.

The two temp cown inserted and screwed up.
After three weeks, the gingival conditioning created by the temporary restoration led to a natural gingival profile and to the creation of a fake papilla between the two crowns.

Final metal-ceramic restoration.
